

Introduction

Problem Statement

The short-term rental market has become increasingly competitive, with investors needing reliable insights to identify profitable locations and property strategies.

Traditional investment decisions often rely on assumptions such as:

- Popular tourist destinations always generate higher returns.
- Expensive properties always provide better revenue.
- More amenities always increase customer satisfaction.

However, Airbnb profitability depends on multiple factors including:

- Location
- Property type
- Seasonality
- Customer demand
- Pricing
- Reviews
- Property characteristics
- Host performance

Therefore, this project aims to build an analytical framework that supports investment decisions using historical Airbnb data.
